FRONT MATTER

Document information

Field	Record
Project	CLICK / WorldClick
Document	Whitepaper V2.7
Language	English
Document owner	Marku al-Wadiana; editorial ownership only, not identification of a legal issuer
Publication date	10 November 2026
Maximum planned supply	1,000,000,000 CLICK
Planned network	Solana
Fundraising architecture	Planned Public Offering accepting SOL and USDC
Market-launch architecture	Planned Meteora Dynamic Bonding Curve; one quote mint per pool
Offering status	Planned; not open
Token status	TBD; no project mint verified
Issuer and jurisdiction	TBD
Source of allocation data	source/tokenomics.json

Reading conventions

Implemented means functionality that exists and has been verified. **Planned** means functionality on the roadmap that is not yet available. **Potential** means a concept that may be explored without a delivery commitment. TBD means a decision or verifiable identifier that has not been finalized. A date written for this document is an editorial publication date, not a launch date.

This edition distinguishes protocol capabilities described by official documentation from CLICK's intended configuration. Meteora, Solana, wallet providers and other third parties operate independently. Reference to their technology does not imply endorsement, integration completion or legal approval.

Version history

Version	Editorial scope
V2.6	Previous project design, preserved separately as the authoritative source for the preceding edition.
V2.7	Reconciled one-token model; nine-allocation tokenomics; structured Public Offering; hybrid vesting; separate Meteora DBC market launch; conditional revenue-funded buybacks; expanded security, legal and risk disclosures.

Important notice

This is a technical and editorial planning document, not a prospectus, financial promotion, offer to sell securities, investment recommendation, legal opinion or tax advice. It must not be used as the sole basis for a financial decision. The issuer, jurisdiction, eligibility, offering terms and legal treatment remain TBD. Any future offering requires its own final terms and qualified legal review.

FRONT MATTER

Abstract

CLICK / WorldClick proposes to turn a universally understood action—pressing a button—into a multilingual global participation experience. WorldClick is the application layer: clicks, points, profiles, country rankings, seasons, tournaments and community initiatives. CLICK is the single planned fungible token on Solana, with a maximum planned supply of **1,000,000,000 CLICK**. Ordinary clicks remain application-level events; they do not create individual blockchain transactions, tokens, revenue or donations.

The economic architecture separates a structured **Public Offering** from subsequent **market price discovery through Meteora Dynamic Bonding Curve (DBC)**. The offering reserves **200,000,000 CLICK (20%)**, accepts SOL and USDC at the offering-accounting level, uses a soft cap with a verifiable refund path, and applies a hybrid vesting model. The separate DBC allocation is **150,000,000 CLICK (15%)**. Each DBC pool selects one quote mint; SOL and USDC are not interchangeable quote assets in one pool. All commercial and curve parameters not yet approved are TBD.

The model is designed to fund development without treating token allocations as cash or trading fees as assured income. Buyback and burn operations may use only a future-approved share of eligible net revenue actually received. They may never use offering proceeds, borrowed funds, forecast revenue, token allocations, refund liabilities or artificial activity. No fixed buyback percentage or cadence is approved.

Country competitions can connect participation with published rewards and carefully governed impact initiatives. The **100,000,000 CLICK** Impact & Philanthropy allocation is a token reserve, not a guaranteed fiat donation. Beneficiary selection, funding, transfer and evidence must be independently defined and disclosed. The project's credibility therefore rests not on automatic economic promises, but on explicit separation of application activity, fundraising, liquidity, realized revenue and verifiable philanthropy.

Keywords: WorldClick; CLICK; Solana; public offering; soft cap; hybrid vesting; Meteora DBC; tokenomics; tournaments; philanthropy; treasury transparency.

FRONT MATTER

Executive Summary

WorldClick starts with a deliberately accessible interaction and adds structure around it: persistent participation, country attribution, recurring seasons and defined competitions. Its simplicity is an onboarding advantage, not evidence of a sustainable economy. The product must earn continued use through reliable scoring, accessible language experiences, fair competition and credible operations.

The project has two layers but one token. WorldClick is the product and participation environment; CLICK is the blockchain asset. Application points and country scores are not token balances. The system does not need a second reward or governance token, and token ownership does not automatically confer corporate, treasury or charitable voting rights.

Approved allocation framework

The maximum planned supply is divided into Public Offering **20%**, DBC launch curve / initial liquidity **15%**, market making / future liquidity **12%**, seasons and tournament rewards **8%**, Treasury & Development **10%**, Team **10%**, Community & Ecosystem **10%**, Impact & Philanthropy **10%**, and Strategic Reserve **5%**. Automated checks confirm that the nine amounts total exactly **1,000,000,000 CLICK** and **100%**. The offering and DBC amounts are distinct and are never combined to imply a larger sale or liquidity allocation.

Financing and market launch

The Public Offering is a planned program-controlled fundraising process, not a request to send assets to an unidentified wallet. A participant would connect an explicitly supported Solana-compatible wallet, review the final terms, select SOL or USDC, sign a transaction and receive a verifiable allocation record. The offering closes into either settlement or a failed/refund state according to its soft-cap rules. Price, caps, dates, eligibility, contribution limits and all vesting values are TBD.

Meteora DBC is a separate mechanism for market launch. It uses a virtual pool and configured curve for price discovery before migration to a DAMM pool under the selected configuration. CLICK plans DAMM v2, subject to final configuration. The offering price does not fix the market-opening price; offering participants receive neither guaranteed liquidity nor guaranteed profits.

Treasury discipline and impact

Reserved tokens are not operating cash. Funding for developers, infrastructure, security and operations depends on the resources actually available after a lawful settlement and on subsequent realized revenue. Buybacks are conditional on eligible net revenue, not on clicks or forecasts. The share assigned to them is TBD.

Competitions may combine token-reserve rewards and externally funded prizes only when each source is stated in advance. A country-linked impact process may allow eligible competition participants to select among vetted beneficiaries under published rules. Such a ballot is not token-holder governance. Donations require an explicit source of funds and evidence; clicks alone do not create them.

The roadmap is gated by readiness rather than promised dates: **Foundation and Preparation Public Offering Market Launch WorldClick Public Launch Expansion**. Every date is TBD. The immediate priorities are legal architecture, secure program development, final offering terms, independent review and transparent treasury controls. Document generation is not evidence that any of these milestones is production-ready.

SECTION 1 / TECHNICAL WHITEPAPER

1. Introduction

Digital participation often becomes complex before it becomes meaningful. WorldClick takes the opposite approach: one action is immediately understandable, while accounts, rankings, languages, seasons and impact initiatives provide depth around it. A person can understand the central interaction without understanding blockchain. Token interaction remains an explicit choice.

This whitepaper defines the intended relationship between that experience and a Solana token. It is not a claim that a finished game or live token exists. Its purpose is to establish an auditable design baseline: what belongs to the application, what belongs on-chain, which allocations are approved, which parameters remain open and which conditions must be satisfied before funds or tokens are handled.

The design follows five principles:

1. **Accessibility before complexity.** Participation should not require a wallet, a transaction fee or technical knowledge for every click.
2. **Explicit economic events.** Purchasing, transferring, claiming or using CLICK on-chain requires a user action and clear transaction terms.
3. **Separate accounting domains.** Offering proceeds, market liquidity, token reserves, operating revenue, prizes and donations are not interchangeable.
4. **No automatic value creation.** Activity does not by itself create revenue, scarcity, a prize or a charitable contribution.
5. **Verification over assurances.** Relevant addresses, vesting rules, protocol configuration, transaction signatures and reports should be publicly checkable once they exist.

Sections 2–6 define the product and supply. Sections 7–11 specify offering, vesting and market structure. Sections 12–18 define treasury, rewards, impact, security and delivery gates. Sections 19–20 address legal constraints and risks. Open parameters are deliberately visible: removing every `TBD` requires decisions and evidence, not editorial embellishment.

SECTION 2 / TECHNICAL WHITEPAPER

2. The WorldClick Concept

2.1 A simple action with structured participation

A WorldClick participant presses a central button and receives application-level feedback under the rules then in force. The backend records eligible events, associates them with an account or session and aggregates points for rankings. The rules may distinguish raw interactions from validated participation. Anti-abuse systems can reject automated, duplicated or otherwise ineligible activity without rewriting history arbitrarily.

The application concept comprises:

- user accounts and profiles;
- clicks, validated points and participation metrics;
- country attribution and global rankings;
- seasons, tournaments and community activities;
- language-aware experiences and local community participation;
- published rewards and impact initiatives.

The exact scoring formula, country-attribution method, season duration and anti-abuse thresholds are TBD. They must be published before the relevant competition. A global ranking is a product construct, not an official measurement of a country's population or public sentiment.

2.2 Language as access, not merely translation

A country-based game naturally crosses linguistic and cultural boundaries. Language support can reduce onboarding friction, make rules understandable and allow local communities to discuss competitions and beneficiary candidates. It can also improve safety: a participant who cannot understand eligibility, prize or wallet instructions is more exposed to mistakes and fraud.

The planned approach is progressive localization rather than an unsupported promise to serve every language at once. Priority languages, review procedures and release timing are TBD. Critical rules should have a designated controlling language, version identifier and consistent defined terms. Community translations can extend reach, but material discrepancies require correction and disclosure. Translation must not silently change economic terms.

Local presentation may adapt examples, number formats, support channels and accessibility needs without manipulating competition scores. Country selection, residence, language and nationality are different concepts; they must not be conflated. Any eligibility or geographic restriction must be based on published product and legal criteria, not inferred from language alone.

2.3 Competition and shared impact

Country rankings provide a shared narrative: individual actions contribute to a larger result. Defined competitions may allocate rewards to eligible winners and, where expressly stated, an impact amount to a vetted initiative associated with the winning country. The competition rules must separate the winner's prize, the impact allocation and the selection process for a beneficiary.

This structure can turn international participation into a reason to learn about local organizations. It does not prove need, effectiveness or legitimacy automatically. Beneficiary due diligence, sanctions screening, consent,

safeguarding and evidence of transfer remain operational requirements. A viral competition is not a substitute for responsible philanthropy.

SECTION 3 / TECHNICAL WHITEPAPER

3. Project Architecture

The ecosystem consists of two conceptual layers with deliberately limited points of contact.

WorldClick — application and experience layer

- interface, accounts and profiles;
- click ingestion and validation;
- points, country scores and rankings;
- seasons, tournaments and participation records;
- community, language and impact processes;
- monitoring, support and application reporting.

CLICK — blockchain token layer

- one planned fungible token on Solana;
- maximum planned supply of **1,000,000,000 CLICK**;
- Public Offering allocation and program accounting;
- hybrid vesting and token claims;
- separate DBC price discovery and liquidity;
- allocation wallets, treasury records and conditional buybacks.

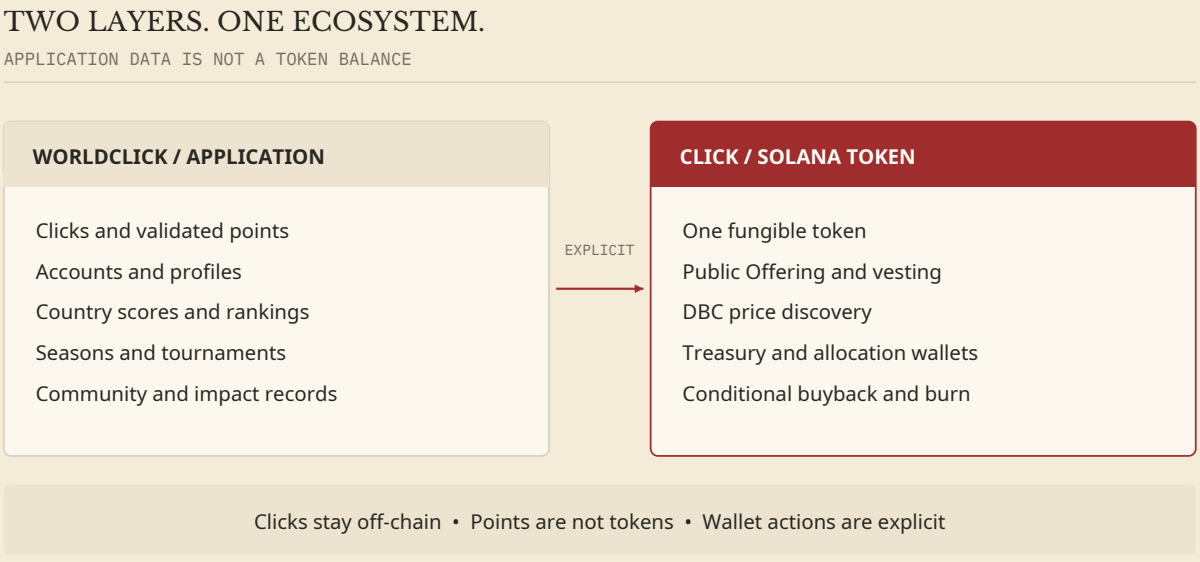

Figure 1. Separation between the WorldClick application layer and the CLICK blockchain layer.

The connection between layers occurs through explicitly designed interfaces, not by treating every application event as a blockchain event. For example, a backend can publish a competition result without putting every underlying click on-chain. A user who chooses to purchase or claim CLICK signs a separate wallet transaction. A wallet can be associated with an account through a signature-based verification flow; the application must never request a seed phrase or private key.

3.1 Single-token boundary

CLICK is the only planned fungible ecosystem token. Points, scores, entries, ranking positions and reputation are application data, not token balances. They may be non-transferable and may be adjusted under published integrity rules. No governance or reward token is part of this architecture.

A single-token model reduces accounting and user-experience complexity. It does not remove the need to define utility carefully. Holding CLICK must not be described as owning WorldClick, receiving a share of its profits, controlling its treasury or having a legally enforceable claim on a competition or charity unless a separate valid mechanism expressly creates such a right.

SECTION 4 / TECHNICAL WHITEPAPER

4. Application Layer and Participation Mechanics

4.1 Ordinary clicks are not blockchain transactions

A click is recorded in the application data layer. It does not require an individual Solana signature or transaction. High-frequency interaction would otherwise create unnecessary cost, latency, network load and wallet friction. Conventional backend infrastructure is appropriate for ingestion, validation, aggregation and ranking.

A click does **not** automatically:

- generate revenue or a token;
- trigger a buyback or burn;
- create a donation;
- guarantee a prize;
- establish ownership of CLICK; or
- prove unique human participation.

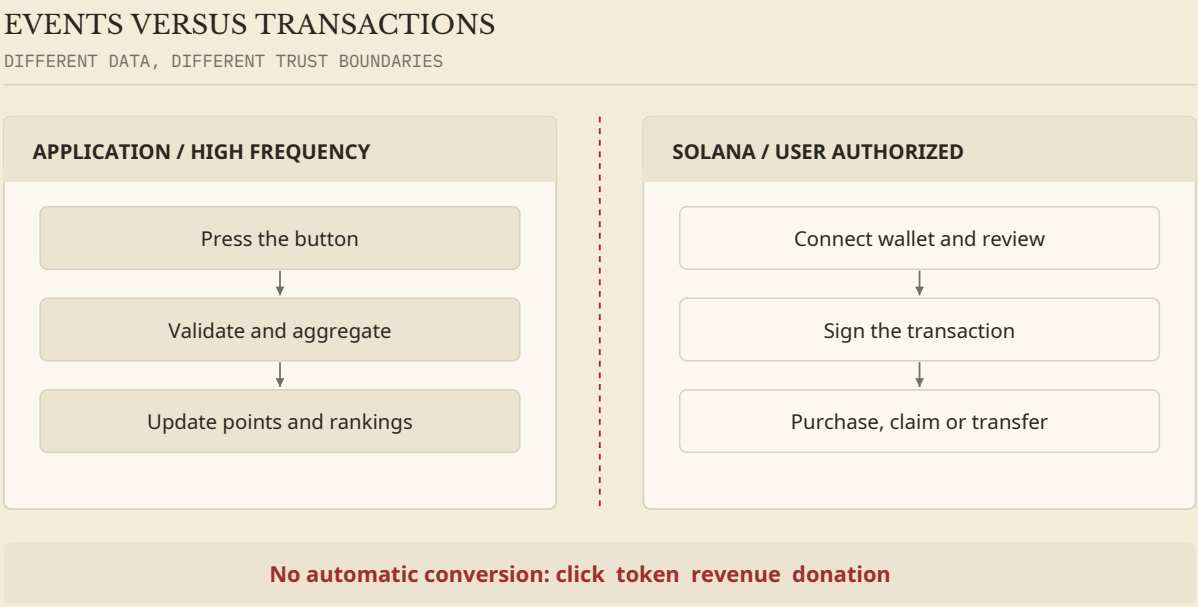

Figure 2. High-frequency application events remain separate from explicit blockchain transactions.

4.2 Participation pipeline

The planned participation pipeline is:

1. The client submits an interaction with a session or account context.
2. The backend applies authentication, schema validation, rate limits and integrity checks.
3. Eligible activity is recorded with an event identifier and timestamp.
4. Aggregation services update points and rankings under versioned scoring rules.
5. Risk systems flag anomalies for review, exclusion or escalation according to published procedures.

6. Competition settlement uses a defined snapshot, eligibility list and appeal or correction process.

“Verified click” should therefore mean an application event accepted under specified controls, not an infallible proof of humanity. Device signals and behavioral analysis can be probabilistic and may produce false positives or false negatives. Privacy impact, retention and access to review must be considered before deploying invasive device fingerprinting.

4.3 Accounts, wallets and country attribution

An application account and a blockchain wallet are separate identifiers. Linking them should use an explicit signed message that contains the intended domain, action and a short-lived challenge. The backend verifies the signature and prevents replay. Wallet connection alone must not authorize unrelated purchases or transfers.

Country attribution may use a user-selected affiliation or another approved method, subject to competition rules. If proof of residence or other eligibility checks are legally required, their scope and privacy implications must be assessed. Raw identity documents should not be written to a public blockchain. The method for changing country, handling disputed attribution and preventing multi-account abuse is TBD.

4.4 Data integrity and availability

Rankings require an authoritative event store, idempotent processing, monitored aggregates and recoverable backups. Corrections should be attributable to a reason and an authorized operational process. Public leaderboards can expose aggregates without exposing private event histories. A public data dashboard should distinguish live, delayed and final values.

No smart contract can repair an incorrect off-chain score by itself. Product credibility depends as much on backend controls, rule clarity, support and incident handling as on token-contract security.

SECTION 5 / TECHNICAL WHITEPAPER

5. CLICK Token

CLICK is the planned fungible token of the ecosystem on Solana. Its maximum planned supply is **1,000,000,000 CLICK**. Decimal precision, token program, mint address and authority configuration are TBD. No project mint has been verified for this edition.

On Solana, a mint account identifies a token and records global information including supply, decimals and relevant authorities. Token accounts track holdings for a particular mint and owner; an Associated Token Account provides a deterministic default account derived from the owner, mint and token program. The implementation must use the correct token program and mint when deriving accounts and constructing transfers. S1

Token design item	V2.7 status
Name / symbol	CLICK / CLICK
Network	Solana — planned
Fungible ecosystem tokens	One
Maximum planned supply	1,000,000,000 CLICK
Decimals	TBD
Token Program or Token-2022 selection	TBD; compatibility review required
Project mint address	TBD; not verified
Mint authority policy	TBD; publish before mint or launch as applicable
Freeze authority policy	TBD; disclose existence, control and rationale
Metadata and upgrade controls	TBD
Initial circulating supply	TBD; depends on final offering, vesting and liquidity configuration

A maximum planned supply is an allocation ceiling, not a representation of circulating supply or available cash. Actual supply and circulating supply must be reported using a stated methodology. If mint authority is disabled, the fixed-supply property can be verified. If any authority is retained, its powers and controls must not be obscured. Token-2022 extensions, if selected, require explicit compatibility testing with the offering, vesting, DBC and wallet stack; they are not assumed.

CLICK does not represent equity, a deposit, a loan, a claim on company profits or a promise of financial return. Its potential product utility is described in Section 15 and remains separate from market speculation.

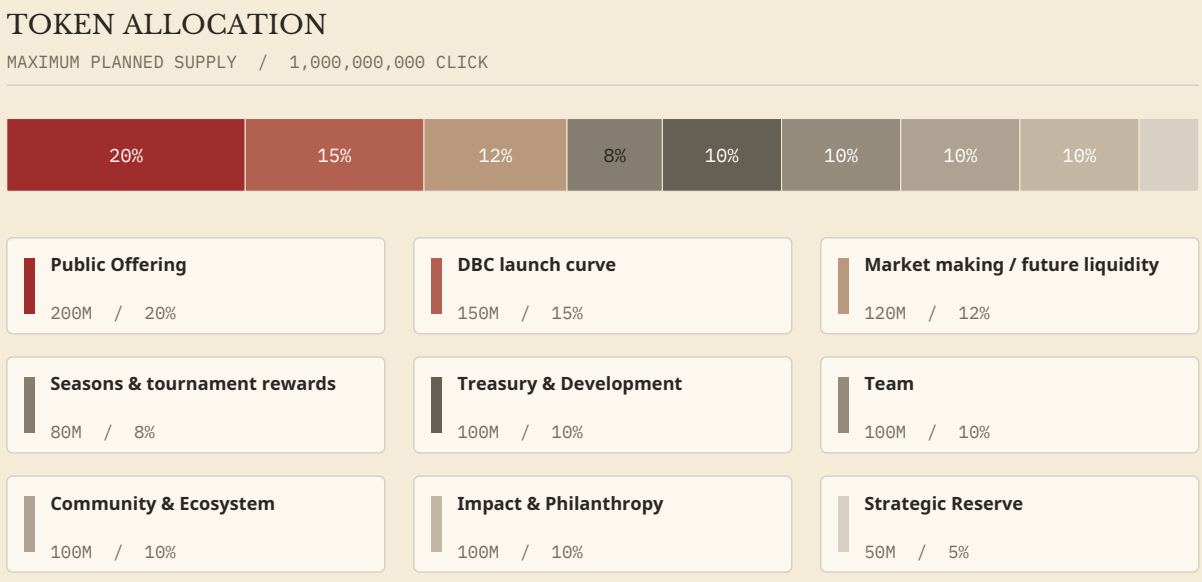

SECTION 6 / TECHNICAL WHITEPAPER

6. Tokenomics

6.1 Definitive allocation for this edition

The following allocation is definitive for V2.7. It describes the maximum planned supply, not the amount liquid on any future launch date.

Allocation	Tokens	Percentage
Public Offering	200,000,000	20%
DBC launch curve / initial liquidity	150,000,000	15%
Market making / future liquidity	120,000,000	12%
Seasons & tournament rewards	80,000,000	8%
Treasury & Development	100,000,000	10%
Team	100,000,000	10%
Community & Ecosystem	100,000,000	10%
Impact & Philanthropy	100,000,000	10%
Strategic Reserve	50,000,000	5%
TOTAL	**1,000,000,000**	**100%**

Allocation initial circulation operating cash. Offering and DBC remain separate.

Figure 3. Allocation of the maximum planned supply; this is not initial circulation or cash.

The machine-readable allocation is maintained in `source/tokenomics.json`. The validation script checks the exact approved rows, unique identifiers, non-negative values, arithmetic and separation of the Public Offering and DBC allocations. In mathematical terms:

```
allocation tokens = 1,000,000,000 CLICK

percentage_i = allocation_i ÷ 1,000,000,000 × 100
```

A failed validation blocks the document build. A successful validation confirms arithmetic and consistency only; it does not verify a mint, custody arrangement or legal approval.

6.2 Allocation purposes and controls

Public Offering — 200,000,000 CLICK (20%). Tokens reserved for the public token offering. The amount allocated to contributors depends on final terms and successful settlement. Treatment of an unsold allocation is TBD and must not be used to enlarge another allocation silently.

DBC launch curve / initial liquidity — 150,000,000 CLICK (15%). Tokens allocated to the Meteora DBC launch stage and its associated liquidity mechanism. This is separate from the offering. Curve use, migration base amount and leftover treatment are TBD.

Market making / future liquidity — 120,000,000 CLICK (12%). Reserved for future market liquidity operations and ecosystem liquidity requirements. It is not an automatic market-support budget. Venue, counterparties, custody, conflicts, release conditions and reporting are TBD.

Seasons & tournament rewards — 80,000,000 CLICK (8%). Reserved for season-based rewards, tournaments and participation incentives. Distribution must follow published competition rules, eligibility and release limits; the amount is not an immediately distributable prize pool.

Treasury & Development — 100,000,000 CLICK (10%). Supports development, infrastructure, operations and long-term execution. Tokens are not equivalent to fiat operating runway. Any sale or conversion requires an approved treasury policy and disclosure appropriate to its materiality.

Team — 100,000,000 CLICK (10%). Reserved for founders, contributors and team-related allocations. Vesting and release schedules must be published before launch. Team vesting is independent of buyer vesting; no schedule is inferred from the offering model.

Community & Ecosystem — 100,000,000 CLICK (10%). Reserved for community development, integrations, ecosystem expansion and participation initiatives. Specific campaigns and material movements should identify their purpose and source allocation.

Impact & Philanthropy — 100,000,000 CLICK (10%). A token allocation reserved for impact and philanthropic initiatives. It is not a guaranteed fiat donation or an immediately available cash fund. A donation occurs only when a separately funded and evidenced transfer is completed.

Strategic Reserve — 50,000,000 CLICK (5%). Reserved for strategic requirements and future opportunities. Its use requires transparent internal policies and disclosure where appropriate. It must not become an undisclosed discretionary wallet.

6.3 Allocation reconciliation and changes

Each future allocation wallet or vesting account should map to one row above. A transfer between allocations does not change total supply, but it changes the approved distribution and must be documented with the reason, authorization, effective date and updated records. No allocation may be counted simultaneously as available for sale, committed to a contributor and reserved for liquidity.

The initial circulating supply cannot be calculated until the offering unlock, settled allocation, DBC configuration and other release schedules are final. “Unlocked,” “circulating,” “liquid” and “held by the public” are not synonyms. The transparency report must define each metric and reconcile it to mint supply and known accounts.

SECTION 7 / TECHNICAL WHITEPAPER

7. Public Offering

7.1 Purpose and status

V2.7 introduces a structured Public Offering to finance development and establish a defined token allocation for eligible participants. The offering is **planned, not open**. Its legal feasibility, issuer, jurisdictions and terms must be approved before any contribution is invited.

Parameter	V2.7 status
Offering allocation	200,000,000 CLICK
Maximum planned supply	1,000,000,000 CLICK
Accepted assets	SOL and USDC
Funding model	Soft cap
Vesting	Hybrid
Offering price	TBD
Soft cap	TBD
Hard cap	TBD
Opening date	TBD
Closing date	TBD
Minimum contribution	TBD
Maximum contribution	TBD
Per-wallet limits	TBD
Eligibility restrictions	TBD
Immediate unlock percentage	TBD
Cliff	TBD
Vesting duration	TBD
Vesting frequency	TBD

The caps must have a stated denomination and accounting treatment. If contributions in two assets are compared with a common cap, the valuation method must be deterministic and disclosed. The soft cap is a minimum funding condition, not a promise that the amount will be sufficient for every roadmap objective. A hard cap limits acceptance under the final rules; it does not create value or guarantee full subscription.

7.2 Intended offering flow

1. The user accesses the official CLICK offering landing page through a verified project channel.
2. The user connects a supported wallet through WalletConnect or another explicitly supported Solana-compatible wallet connection mechanism.

3. The user selects SOL or USDC.
4. The application displays the current offering terms, price, contribution limits and vesting conditions.
5. The user explicitly approves the transaction after reviewing the exact wallet prompt.
6. The offering program validates the contribution against the active state, accepted asset, limits and eligibility rules encoded or authorized under the final design.
7. The contribution is recorded and associated with the buyer's allocation through auditable program accounting.
8. The buyer receives a verifiable allocation record, with transaction confirmation and a clear distinction between pending, settled and claimable states.
9. Once the offering closes, the program evaluates the soft-cap condition.
10. If the soft cap is reached, the offering proceeds according to its published settlement rules.
11. If the soft cap is not reached, eligible contributors receive refunds according to the published refund mechanism.

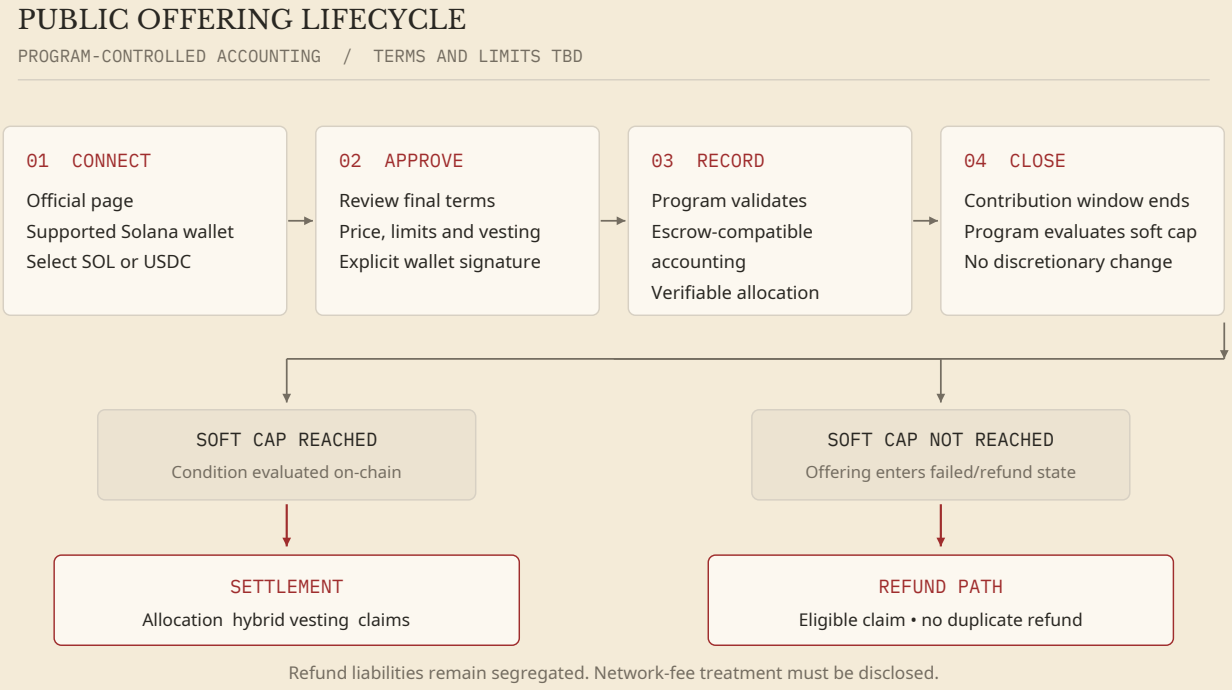

Figure 4. Program-controlled Public Offering lifecycle with settlement and refund branches.

The page must never ask for a seed phrase or private key. A copied address and a request for an ordinary wallet transfer are not an acceptable substitute for program-controlled accounting. A transaction hash alone does not prove the buyer's final entitlement unless it relates to a recognized program state and final terms.

7.3 Program-controlled accounting

The planned program must account separately for each accepted asset and preserve a deterministic record of each contribution. An implementation may use program-derived accounts and escrow-controlled token accounts, but final account architecture is TBD. It must validate the offering state, accepted mint, token program, contributor account, authority, amount, caps and arithmetic. Contributions must be idempotent from the perspective of recorded state; a repeated frontend request must not create an ambiguous allocation.

At minimum, the published technical specification should define:

- offering, contributor and escrow account structures;

- state transitions from draft or inactive to open, closed, successful or failed;
- authority roles and their limits;
- aggregate accepted value and allocated token accounting;
- prevention of contributions outside the approved window and limits;
- final settlement and unsold-allocation treatment;
- claim and refund invariants, including duplicate-claim prevention;
- event logs, error handling and reconciliation procedures;
- upgrade authority and emergency controls, if any.

Contributions should remain subject to the published restrictions until the relevant settlement condition is satisfied. If settlement succeeds, the use of net operational resources must follow the final budget and treasury policy. Offering proceeds are explicitly ineligible for buybacks under Section 12.

7.4 Soft cap and refund conditions

The soft cap establishes the minimum funding threshold for a successful offering. Its value and denomination are TBD. At close, the program evaluates accepted contributions using the published valuation rules. Administrative discretion must not retroactively change that condition.

If the threshold is not reached:

- the offering enters a failed/refund state;
- eligible contributors can claim their refunds through the published mechanism;
- accounting marks each refunded position to prevent a duplicate claim;
- refund transactions and aggregate liabilities are transparent and verifiable;
- the handling of network fees and transaction costs is explicitly disclosed;
- any unclaimed balance remains governed by the published refund policy, not treated as discretionary revenue.

Refund safety requires the escrow to remain solvent for valid claims. Funds reserved for refunds or other liabilities cannot be spent, borrowed against or used for buybacks. Edge cases—failed transactions, contributions after close, blocked participants, wrong mints, account closure and network fees—must be covered in the final technical and legal terms. No refund mechanism can eliminate network, program or operational risk.

7.5 Accepting SOL and USDC

The offering may accept both SOL and USDC because its accounting layer can maintain separate asset records. This is distinct from a DBC pool, which selects one quote mint. Before implementation, the following must be finalized:

Integration requirement	Required final specification
Accepted USDC mint	Exact mint address and token program verified against issuer and official sources; TBD
SOL handling	Native SOL account mechanics or explicitly supported wrapped representation; TBD
Conversion methodology	Common valuation unit, conversion timing and deterministic formula; TBD
Oracle or valuation source	Authoritative source, fallback and governance if conversion is needed; TBD
Staleness	Maximum acceptable price age and circuit-breaker behavior; TBD
Slippage and limits	Transaction bounds, quote expiry and acceptance limits; TBD

Integration requirement	Required final specification
Decimal precision	Base-unit representation, decimal normalization and overflow checks; TBD
Rounding	Contribution, allocation and remainder rounding rules; TBD
Failed transactions	No allocation without confirmed valid state transition; reconciliation procedure TBD

A conceptual allocation calculation is:

```
buyer base-unit allocation = approved_rounding(valid contribution value ÷ offering base-unit price)
```

This equation is incomplete until units, price denomination, valuation, precision and rounding are defined. It must not be implemented with implicit floating-point conversions. If SOL is valued against a stable unit, the design must address price movement between quote display and confirmation. Oracle deviation, stale data and unavailable feeds should fail safely according to published bounds.

The frontend must validate the mint and token program, but backend and on-chain validation remain necessary because a name or symbol is not a unique asset identifier. Wallet simulations, devnet tests and transaction rehearsing should cover both assets and failure paths before mainnet use. Solana transactions execute atomically, but application-level settlement and user expectations still require explicit status reporting. S2

7.6 Offering communications and records

The final offering page must present one authoritative version of the terms, including risk notices, eligibility, vesting, refund treatment and relevant addresses. Material changes require a new version and, where necessary, a new acceptance; they must not be applied retroactively without a lawful and disclosed process.

Public on-chain records should not contain unnecessary personal data. Off-chain eligibility records, support records and marketing consent require separate access controls and retention rules. The user must be able to distinguish a pending allocation, a vested balance, a claimed balance and a transferable wallet balance.

SECTION 8 / TECHNICAL WHITEPAPER

8. Hybrid Vesting

8.1 Model

The Public Offering uses a **hybrid vesting** model. It may combine an initial unlock, a cliff, linear vesting and periodic token releases. The model is intended to make release conditions predictable, not to guarantee a market price or suppress legitimate transfers. All schedule parameters are TBD.

The final offering documentation must publish:

1. immediate unlock percentage;
2. cliff duration;
3. total vesting duration;
4. release frequency;
5. whether vesting starts at offering close, token generation or another defined event;
6. whether claims are permissionless or controlled;
7. whether unclaimed allocations remain in the vesting account; and
8. what happens if the offering fails.

The conceptual sequence is:

```
defined start event (TBD) → initial unlock (TBD) → cliff (TBD) → linear entitlement → periodic claims
```

No numerical schedule is approved by this edition. Any interface showing a schedule before these values are finalized must identify it as non-binding draft material or omit the numbers.

8.2 Claim accounting

A vesting mechanism should use transparent, independently verifiable on-chain accounting. For each settled allocation, the contract must track the total entitlement, schedule, amount already claimed and releasable amount. Conceptually:

```
claimable = max(0, vested entitlement at the current defined time − amount already claimed)

vested entitlement ≤ settled buyer allocation
```

The precise treatment of the cliff, initial unlock, timestamps and rounding is TBD. Claims must not exceed the settled allocation or release tokens before the defined start. The contract must prevent replay and duplicate claims even when a user has multiple transactions or waits across periods.

Permissionless claiming is preferable where lawful and technically feasible because it reduces discretionary custody. If claims are controlled, the authority, conditions and appeal process must be disclosed. Unclaimed allocations should remain attributable to the beneficiary under the published policy; they are not an automatic treasury windfall. If the offering fails, no buyer token vesting should begin and the refund path applies.

8.3 Separate allocation policies

Buyer vesting does not define Team vesting. Team, Treasury & Development, Community & Ecosystem, Impact & Philanthropy, Strategic Reserve, rewards and liquidity allocations each require a disclosed custody and release policy appropriate to their purpose. Those schedules are TBD unless expressly stated otherwise. The Team schedule must be published before launch.

A summary dashboard should show total allocated, vested, claimed, locked and remaining amounts by wallet or vesting account. Manual releases should be avoided where deterministic contracts can implement the approved rules. Any emergency power or upgrade mechanism must be narrow, controlled and visible.

SECTION 9 / TECHNICAL WHITEPAPER

9. Solana Technical Architecture

9.1 Component model

The intended system comprises ten components:

1. **WorldClick frontend.** Participation interface, language presentation, account interactions and explicit wallet flows.
2. **Backend and application data layer.** Event ingestion, validation, profiles, scores, rankings, seasons and operational reporting.
3. **User identity and wallet connection.** Account authentication, nonce-based wallet linking and supported Solana wallet adapters.
4. **Solana CLICK token mint.** Token configuration, supply and authority policies; project address TBD.
5. **Public Offering program.** Contribution validation, escrow-compatible accounting, caps, state transitions and settlement or refund logic.
6. **Vesting program or compatible mechanism.** Deterministic entitlement and claims with independent accounting.
7. **Meteora DBC pool.** Configured virtual pool for separate market price discovery.
8. **Post-migration liquidity mechanism.** DAMM v2 destination, subject to final configuration, and disclosed liquidity ownership or control.
9. **Treasury and allocation wallets.** Segregated custody, identifiable ownership and controlled authorities.
10. **Monitoring and reporting.** Backend health, program events, reconciliation, security alerts and public evidence.

9.2 Trust boundaries

The frontend is an untrusted presentation layer: users can modify it, replay requests or bypass its validation. Backend services must authenticate and authorize application actions. Solana programs must validate their own accounts, signers, mints, amounts and state transitions rather than trusting frontend calculations. Third-party protocols introduce additional programs, authorities and operational dependencies.

A wallet signature proves authorization by a key, not the legal identity or uniqueness of a person. Conversely, an application login must not be treated as authority to move wallet assets. Off-chain administrative actions require least-privilege access and audit logs; on-chain privileged instructions require explicit authority management and, where appropriate, multisignature controls.

9.3 Data and transaction observability

Application monitoring should measure accepted and rejected events, scoring latency, anomalous activity and ranking consistency. Blockchain monitoring should index confirmed relevant transactions, program events, escrow balances, refund liabilities, vesting claims and allocation accounts. Reconciliation must distinguish observed chain state from internal records and escalate discrepancies.

Solana payment flows require validation of the wallet, mint, token program and token account. Associated Token Accounts can require account-creation funding, and network or priority fees may apply. The final interface must explain who pays those costs. S2

No private keys, seed phrases, credentials or private eligibility records belong in this whitepaper, the frontend bundle or public transparency reports. Public addresses are published only after ownership and purpose have been verified; all project addresses remain TBD.

SECTION 10 / TECHNICAL WHITEPAPER

10. Meteora DBC Launch

10.1 Role in the architecture

The planned market launch uses **Meteora Dynamic Bonding Curve (DBC)**, separate from the Public Offering. DBC is Meteora's permissionless token-launch product: a virtual pool supports swaps against a configurable curve, and the configured quote-reserve threshold governs graduation to a Meteora DAMM pool. The official documentation describes DAMM v2 migration for new configurations. S3 S4

The allocation reserved for this stage is **150,000,000 CLICK — 15% of maximum planned supply**. It does not include any of the **200,000,000 CLICK** Public Offering allocation. Tokens may serve both curve and associated migration-liquidity functions only under the final configuration; they cannot be counted twice as independent balances.

10.2 Intended high-level flow

1. The CLICK token mint and token configuration are established and published.
2. The DBC pool is created and configured using the selected compatible setup.
3. A single quote mint is selected for that pool.
4. The initial curve parameters are configured and disclosed.
5. The pool supports price discovery through the configured dynamic bonding curve.
6. The configured migration condition is monitored using verifiable pool state.
7. When the migration condition is met, liquidity migrates according to the selected Meteora configuration.
8. The post-migration liquidity mechanism is documented and made publicly verifiable.

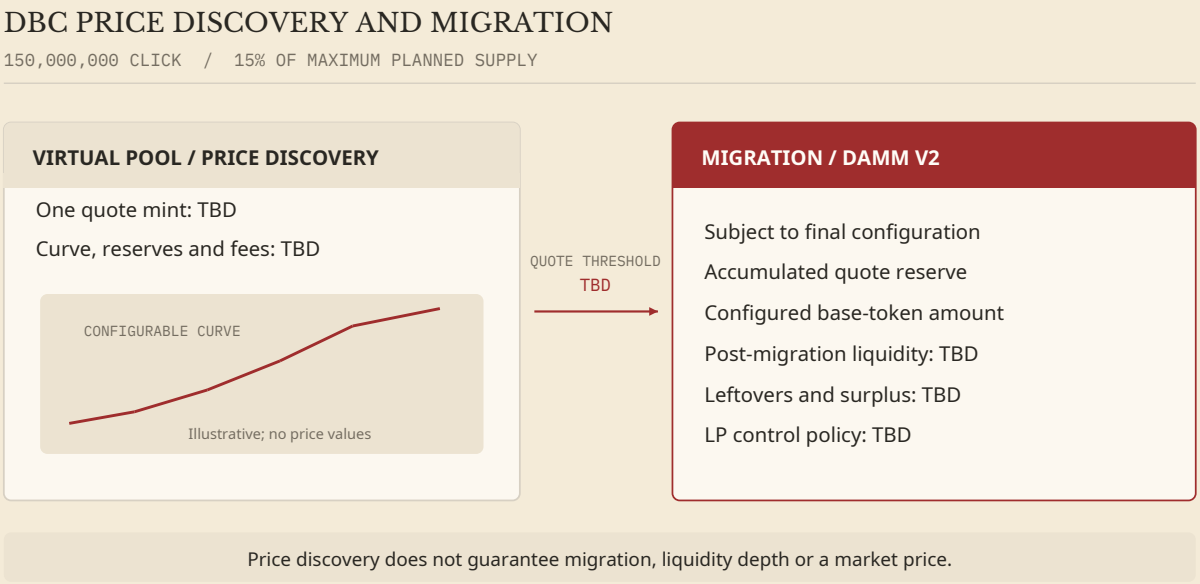

Figure 5. DBC virtual-pool price discovery, configured threshold and intended DAMM v2 migration.

During the curve phase, buys and sells interact with virtual-pool state and the configured reserves and fees. Accumulated quote assets and the configured base-token amount can seed the migrated pool. Once the curve is complete, normal DBC swaps stop and the migration and cleanup processes apply. The exact result depends on configuration; a curve reaching its condition is not a guarantee of deep or permanent liquidity. S3

10.3 Configuration to disclose

Parameter	Status
Quote mint	TBD; exactly one selected for this pool
Initial virtual reserves	TBD
Initial price	TBD
Bonding curve shape	TBD
Curve parameters	TBD
Trading fee	TBD
Creator fee configuration	TBD
Migration threshold	TBD
Migration destination	DAMM v2, subject to final configuration
Liquidity treatment after migration	TBD
Leftover token treatment	TBD
Surplus funds treatment	TBD
LP locking / control policy	TBD

Curve shape, fees, migration and liquidity distribution materially affect participant outcomes. They must be selected using official formulas and tested integration code, not copied from illustrative examples. The final configuration record should include the selected program and config references, token type, quote mint, reserves, curve segments, fee mode, migration parameters and all relevant claim or control accounts. No CLICK-specific values are asserted here.

DBC supports configurable economics and multiple token types, but a protocol capability is not proof of compatibility with an arbitrary custom setup. The selected CLICK token program and any extension must pass integration tests. Program IDs, SDK versions and migration procedures must be verified against current official Meteora materials at implementation time.

10.4 One quote mint per pool

A single DBC pool must not be described as accepting SOL and USDC interchangeably as quote assets. The selected quote mint is TBD. Accepting both at the Public Offering does not change this constraint.

If separate markets are ever considered, each requires its own explicit configuration, allocation reconciliation and disclosures; fragmented liquidity and price differences would need to be addressed. This edition does not approve an additional pool or token.

10.5 Surplus, leftovers and control

“Leftover” base tokens and “surplus” quote assets are configuration- and lifecycle-specific concepts, not free revenue that can be diverted without policy. Their permitted recipients, claims and timing are TBD. Treatment must be consistent with contributor terms, refund obligations, token allocation records and tax or legal requirements.

LP ownership, locks, vesting and claimable fees depend on the selected migration path. A claim that liquidity is locked or burned must be supported by the actual account state and transaction evidence. Until then, the policy remains TBD.

SECTION 11 / TECHNICAL WHITEPAPER

11. Liquidity and Market Structure

11.1 Public Offering versus DBC

The two mechanisms serve different purposes and must not be presented as one combined sale.

Dimension	Public Offering	Meteora DBC
Primary role	Structured fundraising and token allocation	Market launch and price discovery
CLICK allocation	200,000,000 (20%)	150,000,000 (15%)
Assets	SOL and USDC at offering-accounting level	One selected quote mint per pool
Price	Offering price TBD	Determined by configured curve and trading
Allocation record	Program-controlled contributor and vesting records	Pool and swap state
Minimum funding condition	Soft cap TBD; failure enables refunds	Migration threshold TBD; not an offering soft cap
Release conditions	Hybrid vesting; all values TBD	Swaps and migration under final DBC configuration
Liquidity promise	None	None; migration and depth depend on actual configuration and activity

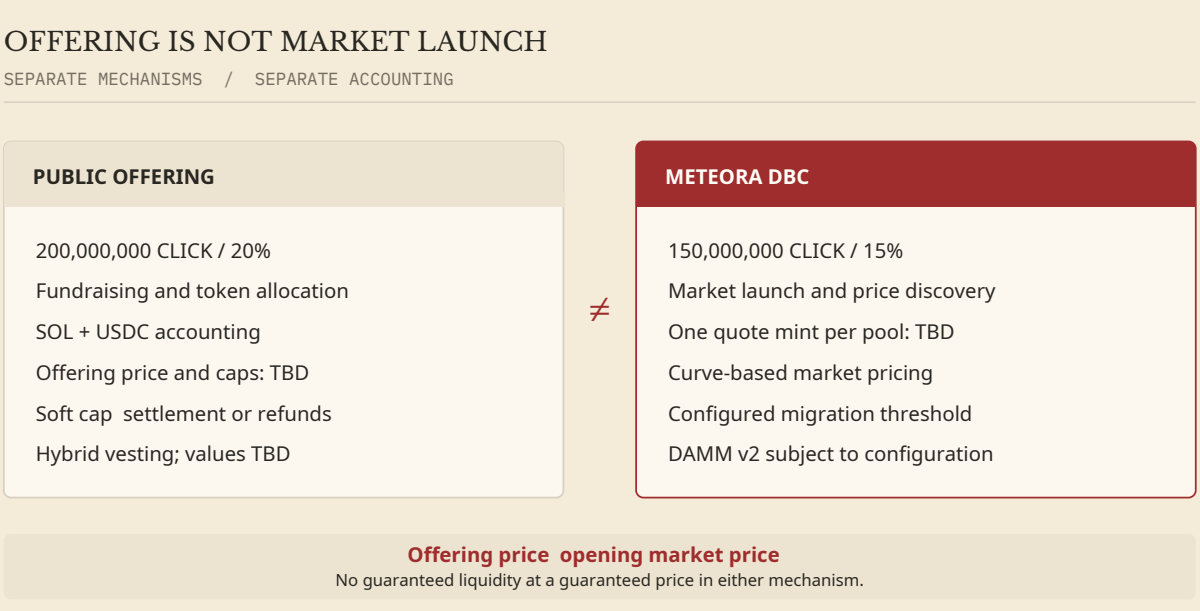

Figure 6. Separate purposes and accounting for the Public Offering and Meteora DBC.

Public Offering participants do not automatically receive guaranteed liquidity at a guaranteed price. The offering price does not guarantee the opening market price, subsequent price or ability to exit. DBC participation does not retroactively alter an offering participant's vesting schedule.

11.2 Circulating supply and liquidity reporting

Before market launch, the project should publish a supply reconciliation showing minted supply, settled buyer allocations, initial unlocks, locked balances, curve inventory, migration liquidity and other allocation accounts. Circulating-supply methodology should be consistent and distinguish transferable but unclaimed entitlements from wallet balances.

Liquidity is not the same as the value of allocated tokens. It depends on executable orders, pool depth, price impact, market conditions and custody arrangements. A market-making reserve does not promise a bid, stable price or protection against loss.

11.3 Conduct and conflicts

Market making and treasury transactions must not use wash trading, fictitious volume, misleading orders or undisclosed manipulation. Agreements with liquidity providers should disclose material terms, related-party conflicts, custody, fees and incentives to the extent appropriate. The project must not present protocol trading fees as recurring operating income before they are actually received and accounted for.

Liquidity operations may expose the treasury to price, counterparty and smart-contract risk. Approval thresholds, execution limits, wallet segregation and reporting are TBD. Any future buyback must follow Section 12 rather than an improvised attempt to support price.

SECTION 12 / TECHNICAL WHITEPAPER

12. Buyback & Burn

12.1 Conditional treasury mechanism

Buyback & Burn is a conditional treasury mechanism under which an approved share of eligible net revenue could be used to acquire CLICK and verifiably burn it. It is not a dividend, yield, contractual price support or guaranteed source of appreciation. The percentage and cadence are TBD.

The only permitted funding source is **eligible net revenue actually received by the project**. Conceptually:

```
R_eligible = max(0, R_received − C − T − F − L − D)
```

Where `R_received` is revenue actually received; `C` is applicable costs; `T` is taxes; `F` is refunds; `L` is liabilities; and `D` is other approved deductions. The accounting policy, approval process and percentage allocated to buybacks are TBD. This formula communicates the order of reasoning, not a finalized accounting standard.

Buybacks may never be funded from:

- Public Offering proceeds;
- borrowed funds;
- unreceived or forecast revenue;
- token allocation balances;
- artificially generated click counts; or
- funds reserved for refunds or other liabilities.

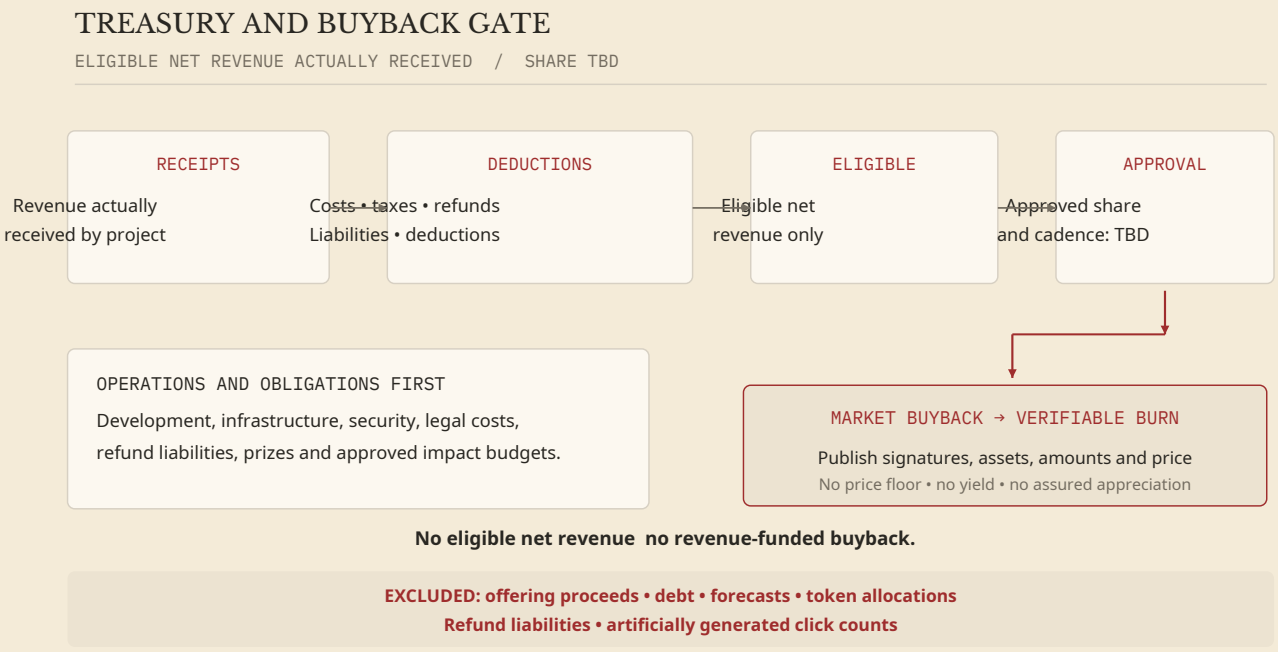

Figure 7. Treasury gate for eligible net revenue and conditional buyback and burn.

12.2 Eligible revenue and runway

Potential future revenue sources may include product purchases, subscriptions, sponsorships, partnerships, marketplace fees or legitimately received protocol-related fees. None is assured. Each source needs recognition criteria, fee and tax treatment, refund treatment and disclosure where material. Gross trading volume, a token's quoted market capitalization and unreceived platform fees are not cash revenue.

Operational resilience comes before discretionary buybacks. Development, infrastructure, security, legal obligations, taxes, refunds and beneficiary commitments require funding under the approved treasury policy. No fixed runway target is approved here. Publishing actual available resources and material obligations is more informative than presenting a large token reserve as cash.

12.3 Execution and proof

If the policy is approved and eligible funds exist, execution should use disclosed risk limits and avoid manipulative or disorderly trading. Venues, execution method, price-impact limits, minimum thresholds, timing and controlling wallets are TBD. No weekly or launch-day cadence is committed.

Where buybacks and burns occur, publish:

- buyback transaction signature;
- date and time;
- asset used;
- amount spent;
- amount of CLICK acquired;
- execution price;
- burn transaction signature; and
- remaining treasury balance, where appropriate and safe to disclose.

The burn method must be technically precise. A token-program burn instruction and a transfer to an inaccessible address are different evidence and may affect reported supply differently. The chosen method and supply methodology must be disclosed, without inventing a burn address. No burn may be described as re-mintable or reversible without verifying the mint and token-program behavior.

12.4 Relationship to clicks

Clicks can be a reporting metric and part of the product narrative. They cannot determine buyback funds. A milestone report may describe participation and separately present realized revenue and transactions, but it must not imply a fixed conversion from click count to tokens burned. Without eligible net revenue, there is no revenue-funded buyback, irrespective of activity.

Reducing token supply does not guarantee a price increase, liquidity, demand or financial return. Participants should evaluate the mechanism as a transparent treasury allocation rule, not as a promise of market performance.

SECTION 13 / TECHNICAL WHITEPAPER

13. Seasons, Tournaments and Rewards

13.1 Published competition rules

Seasons and tournaments are planned participation structures. Each competition should publish its identifier, start and end conditions, eligible participants, country attribution, scoring version, anti-abuse rules, snapshot, tie handling, appeals, prize source, amount or formula, vesting if any, and claim process before participation begins.

Rewards must follow those rules. No participant should assume that raw clicks alone guarantee a prize. The backend may validate or exclude activity, and final results should be reproducible from the published scoring and eligibility criteria. Rule changes after a snapshot require exceptional justification and transparent correction procedures.

13.2 Two distinct funding sources

Source	Nature	Required disclosure
Seasons & tournament rewards allocation	Up to 80,000,000 CLICK reserved over the ecosystem lifecycle; not an immediate cash prize	Allocation account, competition debit, recipient entitlement, release schedule and claim evidence
Actual external revenue or sponsored funds	Fiat, stablecoins or other assets actually received and assigned to a specific prize	Source, amount, fees, custody, payout and transfer evidence

A token-denominated reward carries market and liquidity risk. A sponsored cash prize is not a debit against the token reserve unless expressly accounted for. Mixing the two would overstate available prizes. No fixed season amount or impact percentage is approved in this edition.

13.3 Individual and country results

Individual rankings and country rankings can coexist, but their relationship must be defined. A country score may aggregate eligible contributions without implying that every resident participated or consented. Eligibility for a country-linked prize may differ from eligibility for an individual leaderboard.

Rules should address coordinated farming, multiple accounts, location misrepresentation, bots, collusion and abnormal traffic. Enforcement must be proportionate, logged and subject to review. Security controls cannot be fully disclosed if disclosure would enable abuse, but the criteria and consequences must be understandable.

13.4 Multilingual competition operations

Localized rules and support can broaden participation, but every language version must refer to the same competition identifier and economic terms. The controlling-language provision, correction policy and deadline presentation must be clear. Time zones should be explicit. Local community moderators can help surface misunderstandings without gaining discretionary power over results or prizes.

SECTION 14 / TECHNICAL WHITEPAPER

14. Impact & Philanthropy

14.1 Principles

Impact initiatives may connect a country-winning competition with a vetted beneficiary in or serving that country. This is a potential product and community mechanism, not an automatic legal right, donation promise or token-holder vote. Each initiative requires its own approved budget, beneficiary process and evidence.

Any donation must have an explicitly defined and verifiable funding source. Possible sources include a specifically approved conversion or allocation of resources from the Impact & Philanthropy token reserve, actual external sponsorship, or another disclosed lawful budget. A reserved token amount does not establish its fiat value or liquidity. A commitment should not be announced as completed before transfer.

14.2 Beneficiary selection and country-linked ballots

The project may publish a shortlist of eligible organizations associated with the winning country and conduct a competition-specific community ballot. The selection rules are TBD. They must define who can participate, how eligibility is established, how duplicate or automated voting is limited, the voting window, tie handling and final due-diligence condition.

Token ownership alone does not grant voting rights over charitable funds. If participation-based voting is used, it should be designed around the published competition rules rather than token balance. If a selected organization fails due diligence or cannot receive the transfer, the rules must specify an alternative or rerun process. No smart-contract execution should be claimed unless a verified program actually performs it.

14.3 Due diligence and evidence

Beneficiary review should consider legal status, mission, geographic connection, safeguarding, financial controls, sanctions and legal restrictions, reputational concerns and ability to receive the selected asset. Personal information about beneficiaries, staff or voters must be minimized and protected. An organization's inclusion is not a political endorsement by a country or its population.

For each completed initiative, publish:

- beneficiary selection criteria and process;
- funding source;
- donation amount and asset;
- transfer date;
- transaction reference when on-chain; and
- supporting evidence, such as a receipt or confirmation, where appropriate.

Reporting should distinguish pledged, approved, sent and received amounts. Exchange or conversion costs must be disclosed if relevant. Impact claims should be measurable without exaggerating outcomes that a transfer alone cannot prove.

14.4 Reserve discipline

The **100,000,000 CLICK** Impact & Philanthropy allocation remains a token reserve until used under final policies. Its release schedule and conversion rules are TBD. It is not a guaranteed monetary donation, cannot be spent twice on prizes and operations, and must not be used to finance buybacks. Clicks alone do not generate donations.

SECTION 15 / TECHNICAL WHITEPAPER

15. Token Utility

Token utility must be described according to its actual delivery state. Marketing a concept as available functionality would be misleading.

Classification	Meaning	V2.7 examples
Implemented	Exists and has been verified	No token utility, Public Offering, vesting, DBC integration or public WorldClick game has been verified for this edition
Planned	On the roadmap but not yet available	Token issuance, offering, vesting, market launch and public participation experience
Potential	May be explored; no delivery commitment	Premium features, selected competitions, marketplace integrations, ecosystem incentives and access to selected experiences

Potential future uses may include:

- premium ecosystem features;
- participation in selected competitions where lawful and clearly defined;
- marketplace integrations;
- ecosystem incentives;
- access to selected experiences; and
- other utility introduced through future development.

Each utility requires product rules, pricing, custody, refund treatment and legal analysis as applicable. A wallet-verification mechanism can prove control of an address without exposing a private key, but it cannot guarantee the person's identity or eligibility. Utility should not force every WorldClick user to acquire CLICK or perform an on-chain transaction for ordinary clicks.

Holding CLICK does not guarantee financial returns, prizes, governance rights, access to unimplemented features, a share of project or company profits, a fixed value or the continuation of any particular utility. Changes to utility and material economic terms require clear versioned disclosure.

SECTION 16 / TECHNICAL WHITEPAPER

16. Treasury and Transparency

16.1 Governance boundary

The project is presently described as founder-led. No token-holder governance mechanism has been approved or designed. The token does not automatically grant voting rights over the issuer, treasury, protocol, team or philanthropic funds. Competition-specific beneficiary ballots operate only under their published rules and do not change this boundary.

If governance is proposed in the future, its scope, eligibility, Sybil resistance, conflicts, quorum, execution authority and legal effect would require a separate specification. Informal community consultation must not be presented as binding on-chain governance.

16.2 Wallet and allocation transparency

Once created and verified, the project intends to publish:

- the public CLICK token mint address;
- relevant project and treasury wallets;
- allocation wallets or vesting accounts;
- the offering program and relevant contract addresses;
- the vesting mechanism and claim records;
- the DBC configuration, pool and migration details;
- publicly verifiable burn transactions;
- treasury reports and material movements;
- allocation-specific release policies; and
- relevant audit reports with scope and limitations.

All identifiers are TBD until verified. A public label should not be attached to an address merely because a screenshot or social post associates it with the project. Publication should use an authenticated official channel and preserve a historical record of changes.

16.3 Treasury controls

Treasury assets should be segregated by function and liability. Offering escrow, refund obligations, operational funds, token allocations, prize obligations and impact budgets must not be collapsed into one undifferentiated balance. Approval limits, signer composition, custody providers and emergency procedures are TBD.

A treasury report should reconcile opening and closing balances by asset, material inflows and outflows, committed liabilities, realized revenue, operating expenditure and relevant transaction references. Where publishing an exact balance could create a security or privacy issue, the report should explain the limitation rather than silently omit it. Token balances should not be valued as risk-free cash.

16.4 Reporting cadence and corrections

Reporting frequency is TBD. Material events—offering settlement, refunds, migration, large allocation movements, completed donations and burns—warrant event-based reports even before a periodic report. Corrections should identify the original statement, updated evidence and reason for change without deleting the historical record.

Transparency is not the same as disclosing every operational secret. Security-sensitive signer details, personal data and information that could facilitate abuse require controlled handling. The objective is decision-useful, independently verifiable reporting with explicit limitations.

SECTION 17 / TECHNICAL WHITEPAPER

17. Security and Risk Management

17.1 Security status

No security audit has been evidenced for this edition. Development and review statuses below must not be interpreted as completed controls.

Control area	Status at publication
Offering program audit	TBD; independent review required before handling public funds
Vesting correctness review	TBD; schedule, claims and failure cases require testing
DBC integration testing	Planned; token, curve and migration compatibility not verified
Multisignature controls	Planned where appropriate; signers and thresholds TBD
Treasury segregation	Planned; accounts and policies TBD
Mint and freeze authority decisions	TBD
Program upgrade authority	TBD; disclose control and change process
Monitoring and incident response	Planned; procedures and contacts TBD
Backend and anti-abuse testing	Planned; no production system verified
Legal and compliance review	TBD; qualified review required

17.2 Program security

The offering and vesting programs require threat modeling, least-privilege authorities, checked arithmetic, explicit decimal handling, account ownership validation, signer validation and safe state transitions. Test cases must cover duplicate contributions or claims, incorrect mints, wrong token programs, forged accounts, unauthorized settlement, refund replay, insufficient escrow, rounding, clock manipulation, upgrade misuse and network failures.

An independent audit should identify the exact code revision, deployed program where applicable, dependencies, severity ratings, unresolved issues and remediation verification. “Audited” must never be used without that evidence. Third-party protocol security does not replace review of CLICK's integration and configuration.

17.3 Authority and custody

Mint authority determines whether additional supply can be created. Freeze authority, if present, can restrict token-account transfers and must be disclosed. Offering, vesting and migration programs may have separate authorities; a single key should not silently control all of them. Upgrade authority, if retained, needs controlled signers, monitoring and a disclosed change process.

Multisignature controls reduce single-key risk but introduce signer collusion, availability and operational complexity. Signer diversity, thresholds, key storage, recovery and absence procedures are TBD. Treasury segregation limits blast radius; it does not prevent all fraud or error.

17.4 Oracle and market-data safety

If SOL/USDC contribution accounting uses a price feed, the implementation must validate the expected feed, confidence or deviation bounds, publication time and stale-data behavior. Fallback logic must not accept an arbitrarily old or manipulated price. A pricing outage should produce a defined safe state, not an improvised valuation.

Offering pricing, DBC prices, frontend quotes and treasury reporting may use different timestamps and sources. Each must be labeled. Market-data oracles do not guarantee executable liquidity or eliminate slippage.

17.5 Application integrity and incident response

Anti-abuse controls may include rate limiting, account controls, privacy-conscious device signals, anomaly detection and server-side scoring validation. Operational security also requires dependency management, deployment controls, administrative authentication, encrypted sensitive data, backups and least-privilege access.

An incident-response plan should define detection, severity, decision authority, user communications, evidence preservation, program pause or fallback if supported, refund or prize implications, and post-incident reporting. Public announcements must distinguish confirmed facts from ongoing investigation. A transparent document cannot substitute for rehearsed incident handling.

SECTION 18 / TECHNICAL WHITEPAPER

18. Roadmap

The roadmap is a sequence of readiness gates, not a calendar commitment. **All dates are** TBD**.** Each phase below is **Planned**; none is represented as complete. A phase may be delayed, modified or not proceed if its legal, security, financial or technical conditions are not met.

Phase 1 — Foundation and Preparation

Status: Planned. Timing: TBD**.**

- Final legal and operational structure.
- Token and program architecture.
- Smart-contract development.
- Independent security review.
- Offering documentation and final parameters.
- Public transparency framework.
- Treasury, custody, privacy and incident-response design.

Exit gate: qualified legal review; final approved offering and allocation terms; tested programs; independent security issues addressed or explicitly resolved; verified official communication and wallet-publication process.

Phase 2 — Public Offering

Status: Planned. Timing: TBD**.**

- Publish final offering terms.
- Open the wallet-connected offering interface only after the exit conditions are met.
- Accept eligible SOL and USDC contributions through the program.
- Monitor soft-cap conditions and reconcile escrow liabilities.
- Close the offering and execute settlement or refunds.
- Publish contributor accounting and settlement evidence.

Exit gate: successful final settlement under the published rules, or a failed/refund state with refunds available and duplicate claims prevented. Market launch is not automatic if the offering fails.

Phase 3 — Market Launch

Status: Planned. Timing: TBD**.**

- Publish CLICK mint details and authority configuration.
- Configure Meteora DBC with the selected single quote mint.
- Publish curve, fee, migration and liquidity parameters.
- Initiate price discovery under the final configuration.
- Execute migration according to published conditions.
- Publish liquidity, post-migration control and treasury information.
- Reconcile actual circulating supply and allocation accounts.

Exit gate: verifiable token, pool and allocation records; migration outcome documented if triggered; no unsupported claim that liquidity or a particular price is guaranteed.

Phase 4 — WorldClick Public Launch

Status: Planned. Timing: TBD.

- Release the public participation experience.
- Enable accounts, validated participation and country rankings.
- Introduce versioned participation and anti-abuse mechanics.
- Publish the first global season rules.
- Establish language-review, support and scoring-correction procedures.

Exit gate: tested application availability, published rules, operational support and monitoring. Token functionality must not be confused with application availability.

Phase 5 — Expansion

Status: Planned. Timing: TBD.

- Expand tournaments and language coverage.
- Develop community initiatives and ecosystem integrations.
- Conduct governed impact initiatives with evidence.
- Explore additional utility features.
- Evaluate marketplace and partnership opportunities subject to legal and economic review.

Exit gate: each expansion has its own scope, budget, rules and review. This phase does not imply automatic governance, revenue or utility delivery.

SECTION 19 / TECHNICAL WHITEPAPER

19. Legal and Regulatory Considerations

19.1 Issuer and offering status

The project issuer or legal entity and jurisdiction have not been finalized. No registered address, legal status, regulatory authorization or compliance approval is asserted. All are TBD. Document ownership by Marku al-Wadiana is editorial and does not identify the issuer.

The final offering and token distribution must undergo qualified legal review in the relevant jurisdictions. This includes applicable EU Markets in Crypto-Assets requirements (**MiCA**) where relevant, AML/CFT obligations, sanctions, consumer protection, marketing, privacy, taxation and gaming or competition rules. The analysis must reflect the actual token, communications, fundraising flow, custody, utility, rewards and parties involved.

A third-party launchpad or protocol does not automatically assume the project's legal responsibilities. Describing CLICK as a utility or community asset does not determine its legal classification. No statement in this whitepaper should be interpreted as a legal conclusion.

19.2 Eligibility and jurisdictional restrictions

Eligible participants, restricted jurisdictions, age requirements, sanctions screening and any identity verification are TBD. These terms must be established before the offering and enforced consistently with law and privacy obligations. The public availability of a website or wallet does not mean that participation is lawful everywhere.

If the proposed structure cannot be offered lawfully in a jurisdiction, the project must restrict, modify or postpone the relevant activity rather than relying on disclaimers alone. Participants are responsible for their own independent advice, but this does not remove the project's obligations.

19.3 Consumer, marketing and competition rules

Communications must be fair, clear and not misleading. Token reserves must not be presented as cash, planned features as available products, tentative dates as commitments or philanthropic intentions as completed donations. Risk information must be visible and not hidden behind promotional claims.

Prizes, chance elements if any, paid entry, country competitions and rewards may trigger different gaming, gambling, sweepstakes or consumer rules depending on design and jurisdiction. The final mechanics require specific review. Taxes and reporting may apply to the project, contributors, reward recipients and donors; no universal treatment is asserted.

19.4 Privacy and beneficiary safeguards

Account data, country attribution, wallet links, anti-bot signals, ballot records and eligibility checks require a defined lawful basis, minimization, retention, security and user-rights process under applicable privacy laws. Public blockchains are unsuitable for unnecessary personal data because records can be persistent and widely replicated.

Cross-border philanthropy requires review of beneficiary status, sanctions, anti-money-laundering controls, local donation rules and evidence. The project should not expose vulnerable beneficiaries or local communities to reputational or privacy harm for marketing purposes.

SECTION 20 / TECHNICAL WHITEPAPER

20. Risk Factors

CLICK and WorldClick involve substantial uncertainty. The following list is not exhaustive. Mitigations can reduce but not eliminate risk. A participant could lose the entire value used to acquire CLICK and may be unable to sell or use it.

Risk	Exposure and possible consequence	Planned response or limitation
Token price volatility	Prices can move sharply in either direction; acquisition value can be lost entirely.	No price promises; clear risk disclosures. Market design cannot remove volatility.
Liquidity risk	Limited depth, slippage or no willing buyer may prevent exit at an expected price.	Publish actual configuration and liquidity evidence; no guaranteed market support.
Smart-contract vulnerabilities	Offering, vesting, token or third-party defects can freeze or lose assets.	Independent review, testing and controlled authorities; residual defects remain possible.
Offering failure	The soft cap may not be reached, terms may change or the offering may not proceed.	Program-controlled failed state and refunds; fees, timing and edge cases must be disclosed.
Refund execution	Program defects, insolvency, blocked accounts or network failures may delay refunds.	Segregated escrow accounting, replay protection and reconciliation; no risk-free claim is asserted.
Regulatory uncertainty	Classification or legal changes may restrict issuance, utility, trading or participation.	Qualified review, eligibility controls and scope changes where required.
Jurisdictional restrictions	A user may be ineligible even if a website or pool is technically accessible.	Publish and enforce final restrictions; technical access is not legal eligibility.
Tax implications	Acquisition, rewards, sales, donations and conversions may create tax obligations.	Project accounting and general disclosures; users require individualized advice.
Wallet and private-key risk	Lost keys, phishing, malicious signatures or compromised devices can cause irreversible loss.	Explicit transaction prompts, domain verification and no seed-phrase requests.
Network congestion	Congestion, fees, RPC outages or failed transactions can interrupt contributions, claims and trading.	Status reporting, retry and reconciliation procedures; atomicity does not ensure availability.
Oracle and pricing	Stale, manipulated or unavailable price data can misvalue SOL contributions or display misleading quotes.	Whitelisted sources, staleness bounds and safe failure; exact design TBD.
Market manipulation	Bots, concentrated holdings, wash trading or misleading activity can distort price and volume.	Conduct policies, monitoring and disclosure; public markets remain exposed.
Gaming abuse	Automation, multiple accounts and false country attribution can distort scores and prizes.	Server-side validation, anomaly review and published enforcement; false positives remain possible.
Operational execution	A small team, limited funding, delays or dependency on contractors can prevent delivery.	Readiness gates, budget discipline and transparent status; no delivery guarantee.
Third-party dependency	Wallets, RPCs, oracles, Meteora, hosting and service providers can change or fail.	Version review, fallback planning and monitoring; external parties remain independent.
Treasury and custody	Key compromise, conflicts, insufficient controls or asset sales can harm operations and markets.	Segregation, proposed multisignature controls and reporting; policies TBD.
Vesting and claims	Incorrect schedules, time handling or claims can lock tokens improperly or release excess supply.	Deterministic contracts, independent testing and allocation reconciliation.

Risk	Exposure and possible consequence	Planned response or limitation
Migration and configuration	Incorrect DBC parameters or migration setup can produce adverse pricing or liquidity outcomes.	Official integration references, devnet testing and full configuration disclosure.
Privacy	Account, location, device and wallet data may expose users or be processed unlawfully.	Minimization, security, retention rules and privacy review; public-chain data is persistent.
Philanthropic beneficiary risk	A beneficiary may fail diligence, misuse funds or be unable to receive a transfer.	Vetting, fallback rules and evidence; a donation does not guarantee impact outcomes.
Translation and communication	Inconsistent localized terms or outdated announcements can mislead participants.	Versioned controlling terms, review and visible corrections.
Buyback dependency	Revenue may be absent, execution liquidity poor or burn effects misunderstood.	Only realized eligible net revenue; no fixed cadence, price floor or return promise.

The project may never complete its offering, market launch, application or impact objectives. Readers should not rely on hypothetical future demand, scarcity, sponsorship, revenue or utility. Independent technical, financial, legal and tax assessment is necessary.

SECTION 21 / TECHNICAL WHITEPAPER

21. Project Team

The project has a small founder-led core team. Only the identities and roles supplied for this edition are presented; no additional qualifications, employment history or credentials are asserted.

Member	Role
Marco	Founder
Gustavo	Co-founder
Luis	Team contributor
Barbara	Team contributor

Responsibilities beyond these roles, individual allocations, vesting, wallets and legal positions are TBD where not otherwise published. Team tokens must follow their own disclosed vesting and release schedule before launch. A team allocation is not an immediate salary or cash equivalent.

The team may engage developers, auditors, legal advisers, language reviewers and other contributors as resources and requirements allow. Such engagement must not be represented as completed until verified. Operational capacity, conflicts and key-person dependency remain relevant risks for a small team.

SECTION 22 / TECHNICAL WHITEPAPER

22. Conclusion

WorldClick proposes a clear product idea: a simple action can become a shared international experience when supported by fair participation rules, accessible languages, country rankings and well-governed competitions. CLICK provides a separate token layer without turning every click into a blockchain transaction or an automatic economic event.

V2.7 establishes a disciplined token and launch structure. The Public Offering reserves **200,000,000 CLICK**, accepts SOL and USDC through program-controlled accounting and includes a soft-cap refund path and hybrid vesting. The separate **150,000,000 CLICK** DBC allocation supports planned Meteora price discovery with one quote mint and intended DAMM v2 migration, subject to final configuration. The nine allocations sum to **1,000,000,000 CLICK**, not to a guaranteed cash budget.

Sustainable financing requires more than a token launch. Offering resources, actual product revenue, operating costs, refund obligations and token reserves must remain distinguishable. Buybacks, if approved, depend solely on eligible net revenue actually received. Impact requires an explicit funding source, responsible beneficiary selection and verifiable evidence; the token reserve is not a monetary promise.

The next work is concrete: resolve the `TBD` parameters, complete legal and security review, test failure paths, publish addresses only after verification and make the offering and market configurations independently auditable. The project should proceed only when those conditions are satisfied. No production readiness, token availability, liquidity, financial return or application delivery is claimed by this document.

SECTION 23 / TECHNICAL WHITEPAPER

23. Glossary

Term	Definition in this document
Allocation	A designated share of the maximum planned token supply, not an equivalent cash balance.
Application-level data	Information processed by WorldClick infrastructure rather than individually settled on Solana.
Associated Token Account	A deterministic Solana token account derived from owner, mint and token program.
Burn	A disclosed token-reduction action whose technical method and supply effect must be verifiable.
BUYBACK	A treasury purchase of CLICK using only eligible net revenue under an approved future policy.
Circulating supply	Tokens counted as circulating under a stated methodology; not synonymous with unlocked or liquid.
Cliff	A period before a defined portion of a vesting entitlement becomes available; duration TBD.
CLICK	The single planned fungible Solana token of the ecosystem.
Country score	An application-level aggregate under published competition rules.
DAMM v2	Meteora's dynamic automated market maker version 2; intended migration destination subject to configuration.
DBC	Meteora Dynamic Bonding Curve, a virtual-pool token-launch and price-discovery mechanism.
Eligible net revenue	Revenue actually received less applicable costs, taxes, refunds, liabilities and approved deductions.
Hard cap	Maximum accepted funding under final offering terms; value and denomination TBD.
Hybrid vesting	A combination of possible initial unlock, cliff, linear entitlement and periodic claims.
Implemented	Existing and verified; not merely described or planned.
LP	Liquidity provider; LP ownership or control depends on the selected pool and migration configuration.
Maximum planned supply	The approved V2.7 allocation ceiling: 1,000,000,000 CLICK.
Migration	The configured transition from a completed DBC curve to a Meteora DAMM pool.
Mint account	The Solana account identifying a token and recording global token configuration.
Oracle	A source of external data such as prices, with freshness and manipulation risks.
Planned	On the roadmap but not yet available.
Potential	A concept that may be explored without a delivery commitment.
Public Offering	The planned structured contribution and CLICK allocation process, separate from DBC trading.
Quote mint	The single asset selected for a given DBC pool's quote side.
Soft cap	Minimum offering funding condition; failure leads to the published refund state.
Solana program	On-chain executable logic; referred to as a smart contract in general discussion.
TBD	To be determined; unresolved and not a confirmed fact or identifier.
Token account	An account tracking holdings of a specific mint for a specific owner.

Term	Definition in this document
Vesting	A deterministic schedule governing when allocated tokens become claimable or transferable.
Wallet	Software or hardware that controls keys and displays or signs transactions; not a legal identity.
WorldClick	The application and experience layer, separate from the CLICK token layer.

SECTION 24 / TECHNICAL WHITEPAPER

24. Technical References

Official protocol documentation is the reference for protocol behavior. These sources do not verify CLICK's future configuration or implementation. Accessed **10 November 2026**. Integration teams must re-check current versions, formulas, security notices and deployment identifiers before use.

Final document disclaimer

This whitepaper is a planning document as of its publication date. It is not an offer, solicitation, prospectus or promise of delivery. The final offering documents, verified program addresses, token configuration, risk disclosures and legal review must prevail over earlier drafts where lawfully applicable. No reader should infer regulatory compliance, an active sale, deployed token, completed audit, existing liquidity or production readiness from this publication.
